

ABSTRACT OF THE DISCLOSURE

The present invention relates to a refrigerator, which allows more easy inspection to detect leakage of refrigerant. The refrigerator comprises a body defined with a refrigerating compartment and a freezing compartment therein, a machinery
5 chamber defined at an upper portion of the body and adapted to receive components of a refrigerant cycle therein, first and second evaporators for cooling the refrigerating and freezing compartments, respectively, a first refrigerant pipe extending from the first evaporator, a second refrigerant pipe extending from the second evaporator, an assistant capillary pipe connected between the first and second refrigerant pipes for
10 cooling the refrigerating and freezing compartments to different temperatures, a capillary pipe container provided in the machinery chamber for receiving the assistant capillary pipe therein, and an inspection hole provided at one side of the capillary pipe container for allowing a detection device for detecting leakage of refrigerant to be inserted into the capillary pipe container.
